Notas explicativas

Os líquenes são organismos formados pela associação entre um fungo, o micobionte, e um parceiro fotossintético, geralmente uma alga verde ou uma cianobactéria (raramente ambas), que constitui o ficobionte.

Este trabalho cita todos os líquenes e fungos liquenícolas que foram referidos com confiança para o arquipélago dos Açores (n=788, 10 dos quais endémicos). É baseado na lista anterior (Rodrigues & Aptroot 2005), presentemente com indicação da distribuição das espécies pelas nove ilhas do arquipélago. As alterações à listagem anterior resultam da publicação de novos registos (especialmente Aptroot *et al.* 2009 e Berger & Priemetzhofer 2008, mas considerando igualmente Sérusiaux *et al.* 2007; Ahti & Aptroot 2008; Aptroot 2009; Etayo & Berger 2009), uma reavaliação dos registos anteriores e alguns exemplares do herbário dos autores. A lista contém ainda algumas espécies boreais, que foram referidas há bastante tempo, e para as quais não foi estudado material de herbário.

A taxonomia seguiu, na maior parte dos casos, a moderna flora de líquenes das Ilhas Britânicas (Smith *et al.* 2009), uma flora que tem afinidades com a flora dos Açores.

No texto, a primeira coluna (D) apresenta o estatuto de colonização de cada espécie, tal como se segue:

END – espécies endémicas dos Açores, *i.e.* espécies que ocorrem apenas nos Açores, como resultado de fenómenos de especiação (neoendemismos) ou de extinção de populações continentais (paleoendemismos).

É apresentada a distribuição das espécies ou subespécies nas nove ilhas dos Açores (de oeste para este), usando-se a seguinte simbologia: COR – Corvo; FLO – Flores; FAI – Faial; PIC – Pico; GRA – Graciosa; SJG – São Jorge; TER – Terceira; SMG – São Miguel; SMR – Santa Maria.

Explanatory notes

Lichens are organisms formed by the association between a fungus, the mycobiont, and a photosynthetic partner, usually a green alga or a cyanobacterium (rarely both), which forms the photobiont or phycobiont.

This checklist cites all lichens and lichenicolous fungi that have been reliably reported from the Azores (n=788, 10 endemic). It is based on the previous checklist (Rodrigues & Aptroot 2005), although in this work the distribution of the lichens among the nine Azorean islands is also presented. Changes are based on additional published records (especially Aptroot *et al.* 2009 and Berger & Priemetzhofer 2008, but also Sérusiaux *et al.* 2007; Ahti & Aptroot 2008; Aptroot 2009; Etayo & Berger 2009), a re-evaluation of records and a number of herbarium records from the authors. The list still contains a few boreal species that were reported rather long ago, which have not been seen recently and of which no herbarium material has been studied.

The taxonomy mostly follows the modern lichen flora of the British Isles (Smith *et al.* 2009), a flora which shares many species with the Azores.

The first column (D) gives the colonization status of each species as follows:

END – azorean endemic species, *i.e.* species (or subspecies) occurring only in the Azores, as a result of either speciation events (neo-endemics) or extinction of the mainland populations (palaeo-endemics);

For each species or subspecies, the distribution on the nine Azorean islands is given using the following abbreviations (from west to east): COR – Corvo; FLO – Flores; FAI – Faial; PIC – Pico; GRA – Graciosa; SJG – São Jorge; TER – Terceira; SMG – São Miguel; SMR – Santa Maria.
